

The zeros as eigenvalues of $\hat{H}$ (scale-time evolution generator): $\sigma(\hat{H}) = \{-i(\rho - \frac{1}{2})\}$

$\sigma(\hat{H})$ shows level repulsion: GUE, not Poisson
(eigenvalues of a self-adjoint operator)

density $\frac{dN}{dT} = \frac{1}{2\pi} \log \frac{T}{2\pi} = \frac{1}{2\pi} \log p$
(shell scale-depth = Planck cutoff $\hbar$)
